

# Code Optimization

# Code Optimization

- Requirements:
  - Meaning must be preserved (correctness)
  - Speedup must occur on average
  - Work done must be worth the effort
- Opportunities:
  - Programmer (algorithm, directives)
  - Intermediate code
  - Target code

# Levels

- Window – peephole optimization
- Basic block
- Procedural – global (control flow graph)
- Program level – interprocedural

# Peephole Optimizations

- Constant Folding

`x := 32` becomes `x := 64`

`x := x + 32`

- Unreachable Code

`goto L2`

`x := x + 1` ← unneeded

- Flow of control optimizations

`goto L1` becomes `goto L2`

...

`L1: goto L2`

# Peephole Optimizations

- Algebraic Simplification

$x := x + 0 \leftarrow$  unneeded

- Dead code

$x := 32 \leftarrow$  where  $x$  not used after statement

$y := x + y \quad \rightarrow \quad y := y + 32$

- Reduction in strength

$x := x * 2 \quad \rightarrow \quad x := x + x$

# Peephole Optimizations

- Local in nature
- Pattern driven
- Limited by the size of the window

# Basic Block Level

- Common Subexpression Elimination
- Constant Propagation
- Dead code elimination
- Plus many others such as copy propagation, value numbering, partial redundancy elimination, ...

# Simple example: $a[i+1] = b[i+1]$

$t1 = i + 1$

$t2 = b[t1]$

$t3 = i + 1$

$a[t3] = t2$

$t1 = i + 1$

$t2 = b[t1]$

$t3 = i + 1$  ← *no longer live*

$a[t1] = t2$

Common expression can be eliminated

# Simple example: $a[i+1] = b[i+1]$

Now, suppose  $i$  is a constant:

$$i = 4$$

$$t1 = i + 1$$

$$t2 = b[t1]$$

$$a[t1] = t2$$

$$i = 4$$

$$t1 = 5$$

$$t2 = b[t1]$$

$$a[t1] = t2$$

$$i = 4$$

$$t1 = 5$$

$$t2 = b[5]$$

$$a[5] = t2$$

Final code:

$$i = 4$$

$$t2 = b[5]$$

$$a[5] = t2$$

# Control Flow Graph - CFG

CFG =  $\langle V, E, \text{Entry} \rangle$ , where

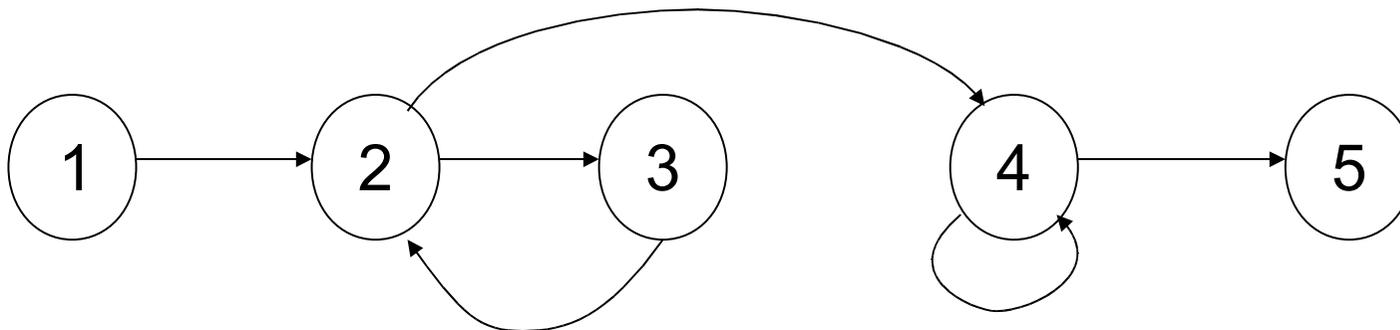

$V$  = vertices or nodes, representing an instruction or basic block (group of statements).

$E = (V \times V)$  edges, potential flow of control

Entry is an element of  $V$ , the unique program entry

Two sets used in algorithms:

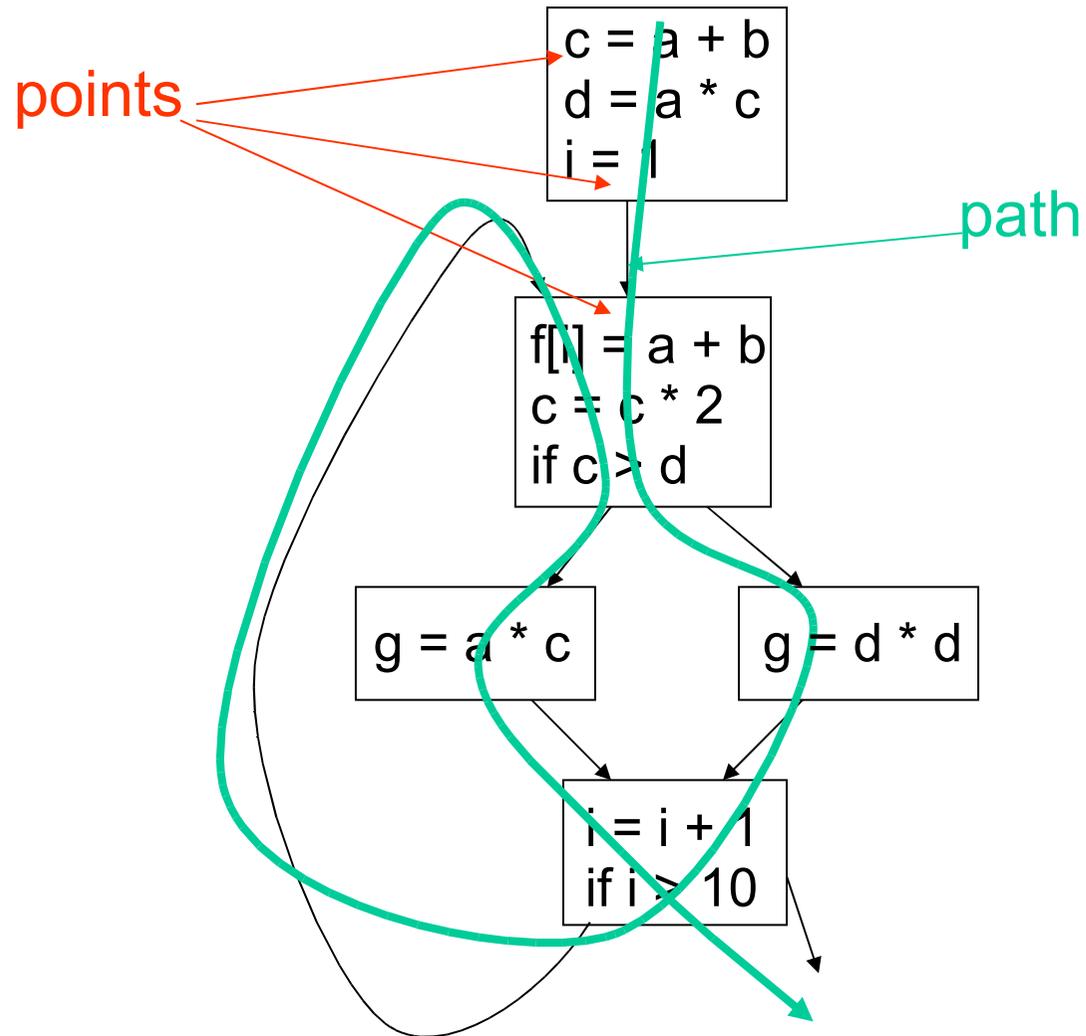

- $\text{Succ}(v) = \{x \text{ in } V \mid \text{exists } e \text{ in } E, e = v \rightarrow x\}$
- $\text{Pred}(v) = \{x \text{ in } V \mid \text{exists } e \text{ in } E, e = x \rightarrow v\}$

# Definitions

- **point** - any location between adjacent statements and before and after a basic block.
- A **path** in a CFG from point  $p_1$  to  $p_n$  is a sequence of points such that  $\forall j, 1 \leq j < n$ , either  $p_j$  is the point immediately preceding a statement and  $p_{j+1}$  is the point immediately following that statement in the same block, or  $p_j$  is the end of some block and  $p_{j+1}$  is the start of a successor block.

# CFG

# Optimizations on CFG

- Must take control flow into account
  - Common Sub-expression Elimination
  - Constant Propagation
  - Dead Code Elimination
  - Partial redundancy Elimination
  - ...
- Applying one optimization may create opportunities for other optimizations.

# Redundant Expressions

An expression  $x \text{ op } y$  is redundant at a point  $p$  if it has already been computed at some point(s) and no intervening operations redefine  $x$  or  $y$ .

$$m = 2 * y * z$$

$$n = 3 * y * z$$

$$o = 2 * y - z$$

redundant

$$t0 = 2 * y$$

$$m = t0 * z$$

$$t1 = 3 * y$$

$$n = t1 * z$$

$$t2 = 2 * y$$

$$o = t2 - z$$

$$t0 = 2 * y$$

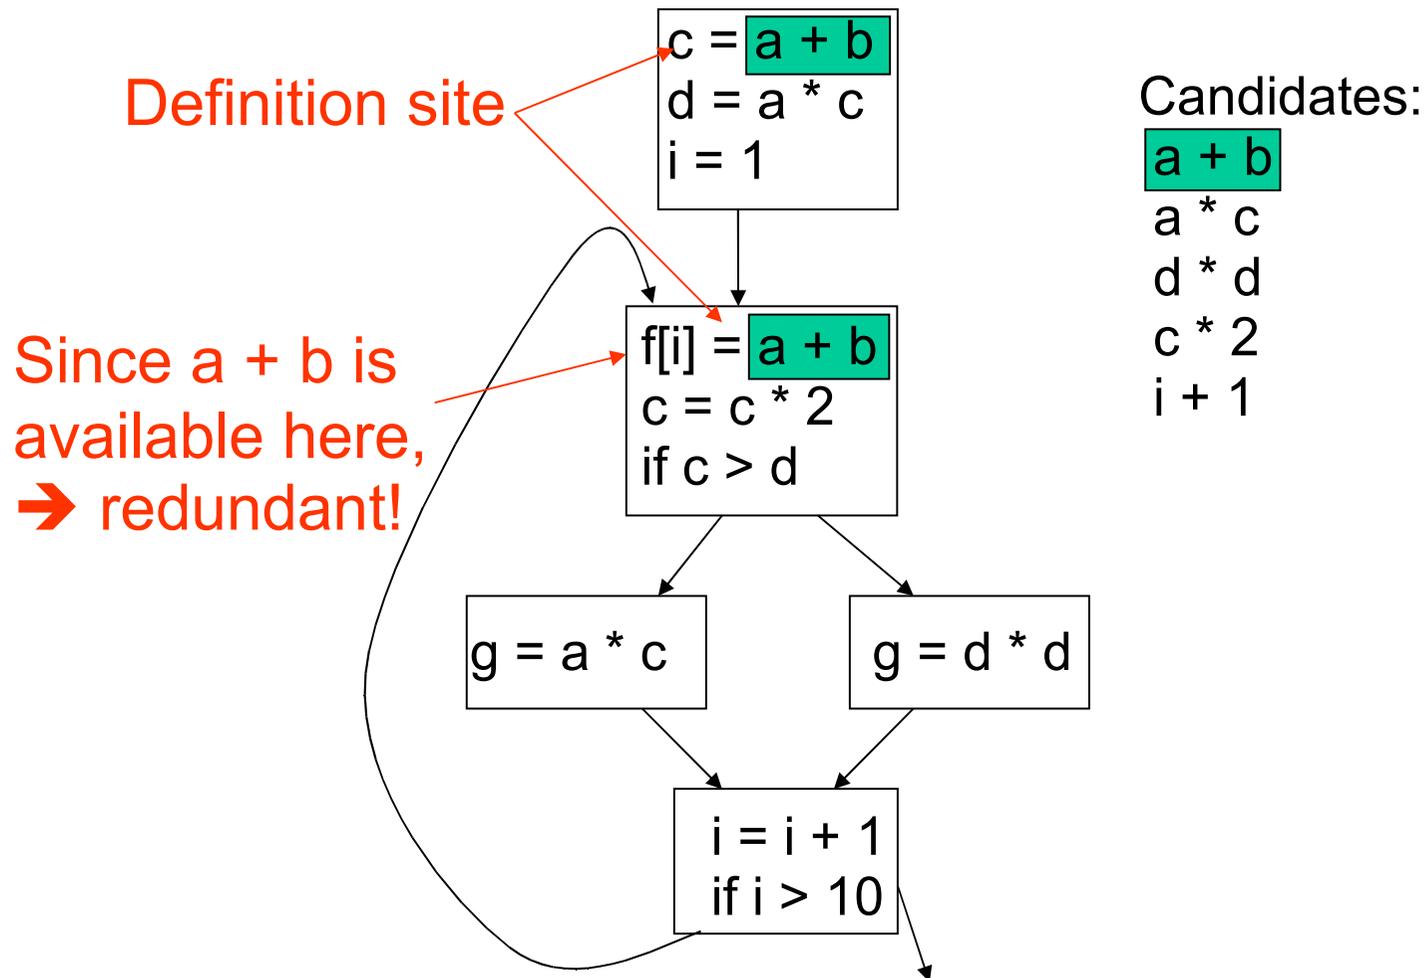

$$m = t0 * z$$

$$t1 = 3 * y$$

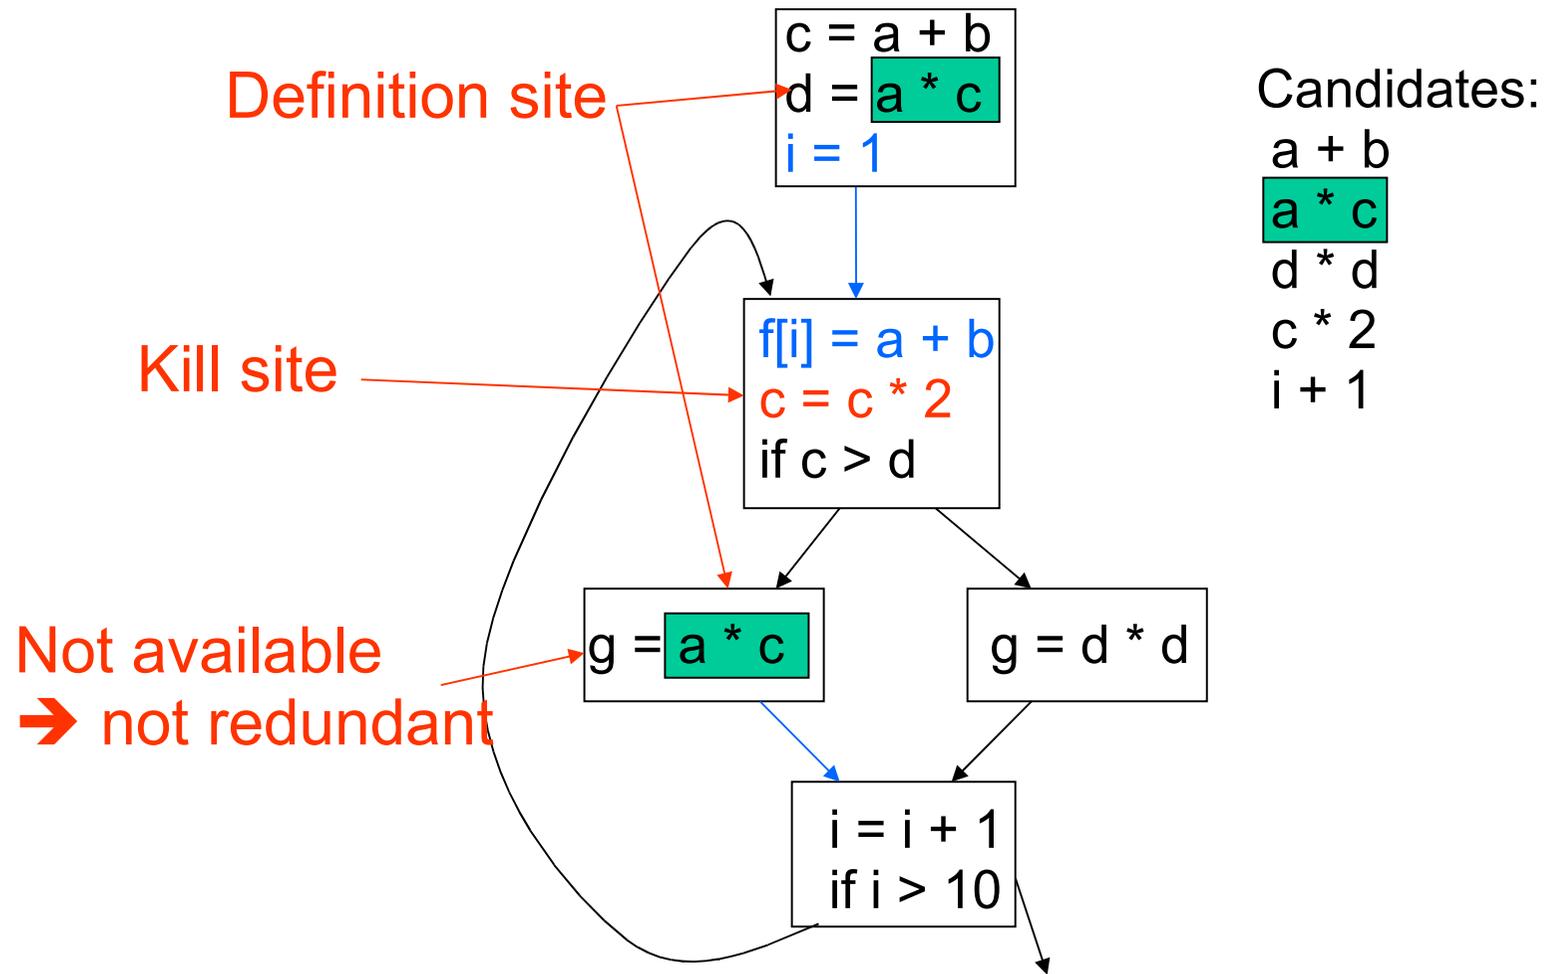

$$n = t1 * z$$

$$o = t0 - z$$

# Redundant Expressions

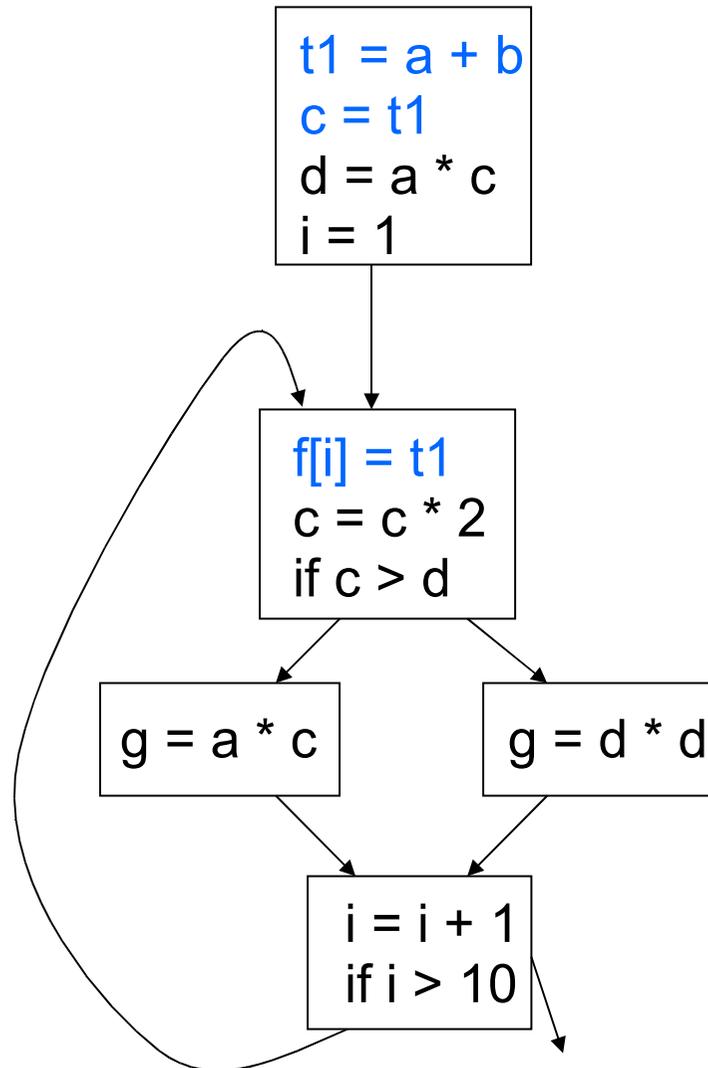

# Redundant Expressions

# Redundant Expressions

- An expression  $e$  is defined at some point  $p$  in the CFG if its value is computed at  $p$ . (definition site)
- An expression  $e$  is killed at point  $p$  in the CFG if one or more of its operands is defined at  $p$ . (kill site)
- An expression is available at point  $p$  in a CFG if every path leading to  $p$  contains a prior definition of  $e$  and  $e$  is not killed between that definition and  $p$ .

# Removing Redundant Expressions

Candidates:

$a + b$

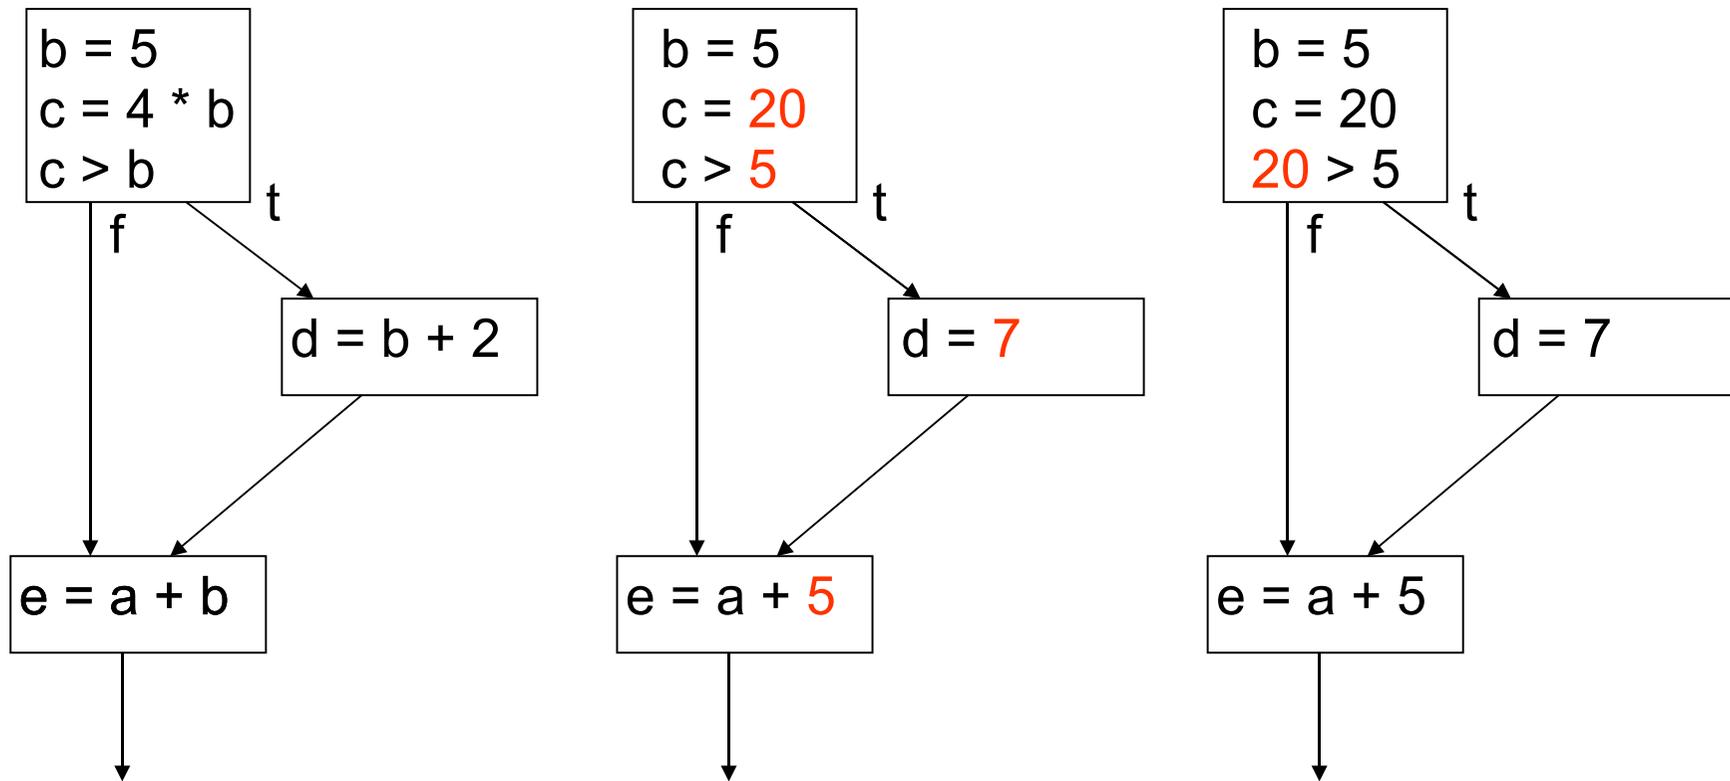

~~$a * c$~~

~~$d * d$~~

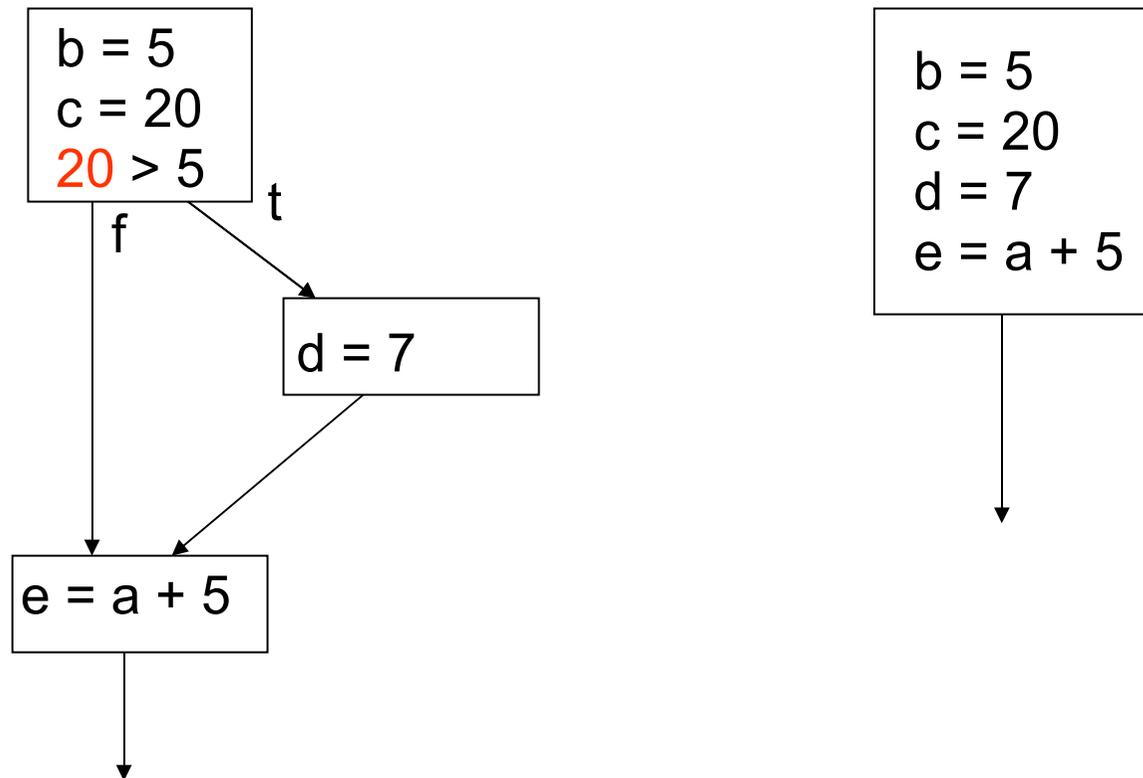

~~$c * 2$~~

~~$i + 1$~~

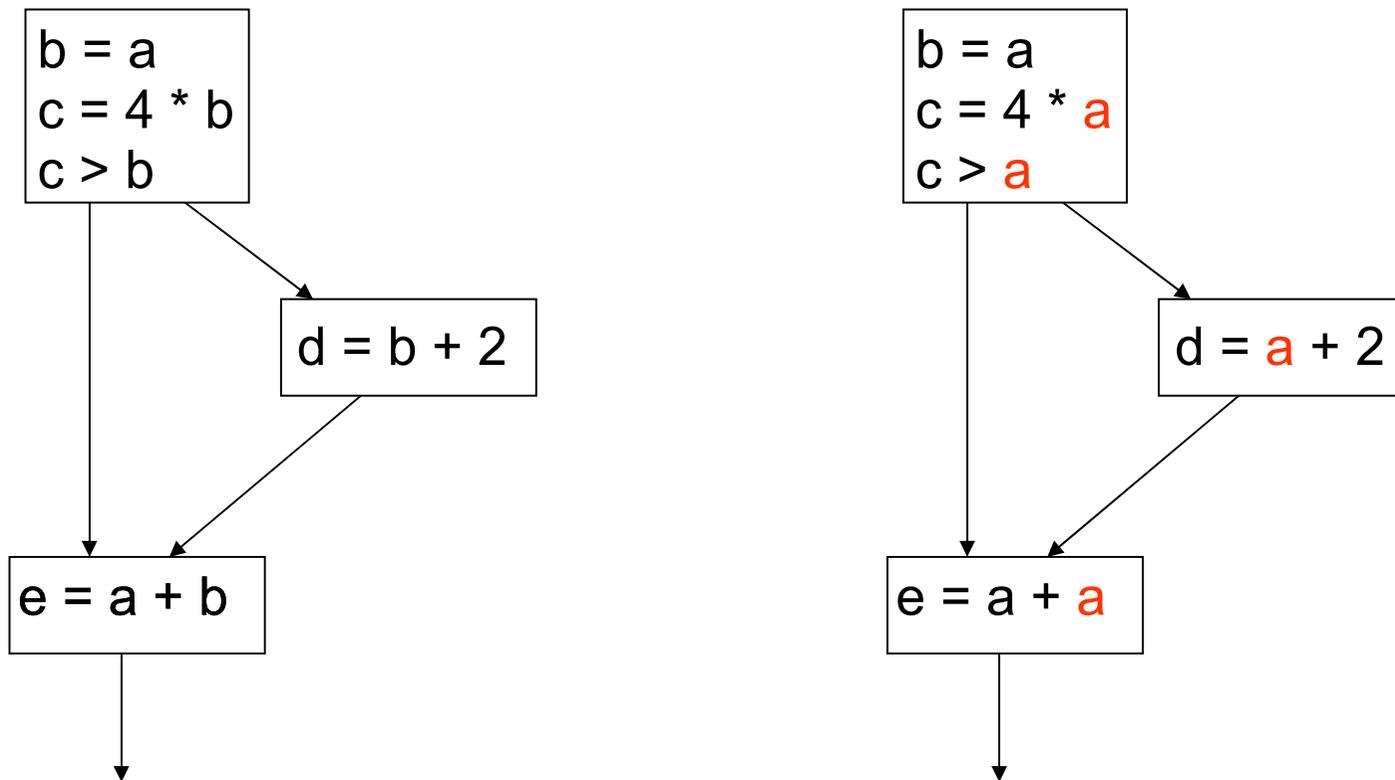

# Constant Propagation

# Constant Propagation

# Copy Propagation

# Simple Loop Optimizations: Code Motion

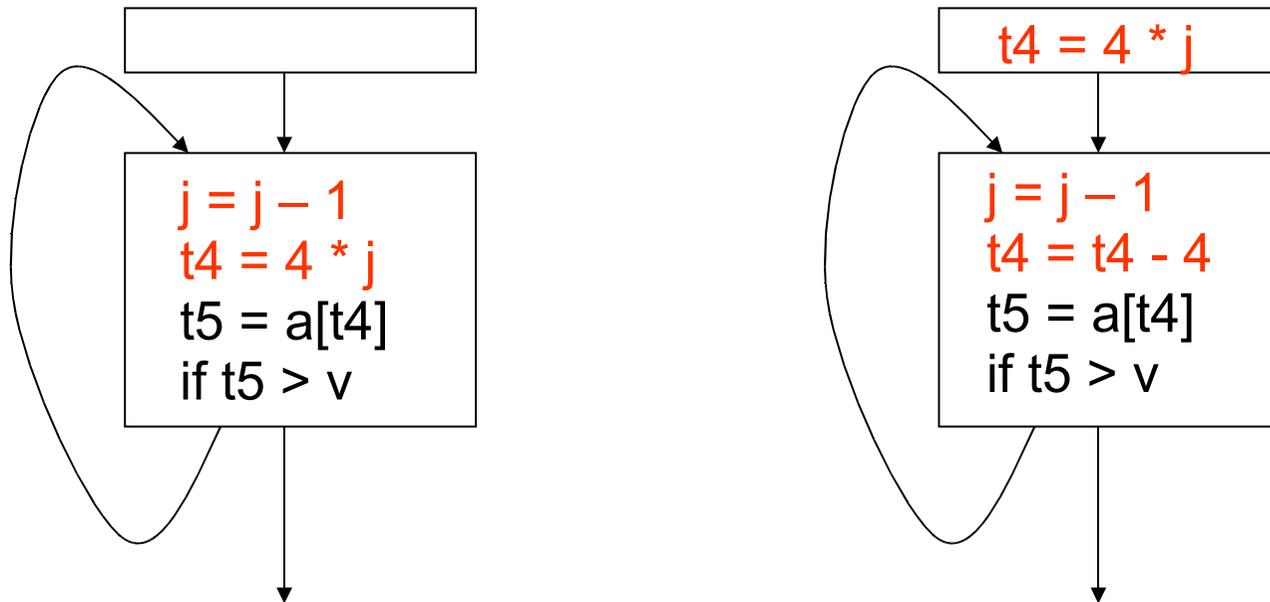

```
while (i <= limit - 2)
    L1:
        t1 = limit - 2
        if (i > t1) goto L2
        body of loop
        goto L1
    L2:
```

---

```
t := limit - 2
while (i <= t)
    L1:
        t1 = limit - 2
        if (i > t1) goto L2
        body of loop
        goto L1
    L2:
```

# Simple Loop Optimizations: Strength Reduction

- Induction Variables control loop iterations

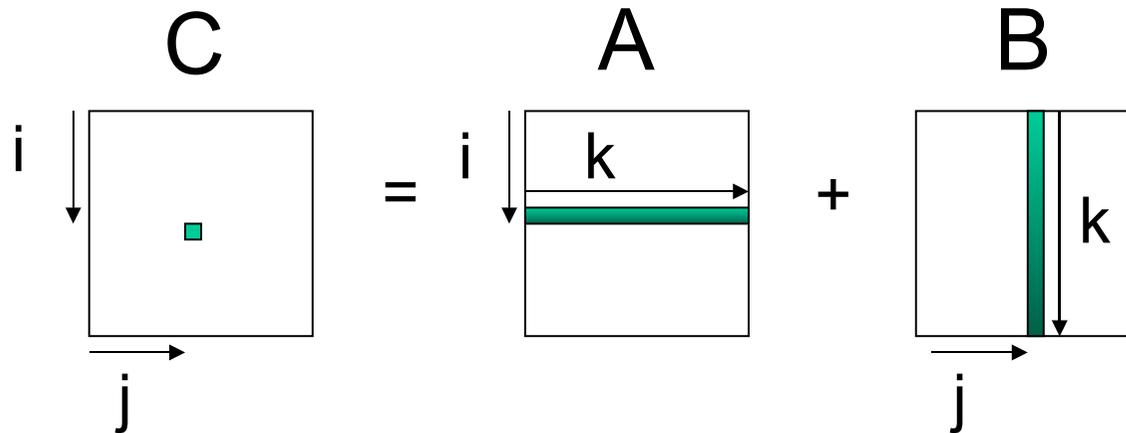

# Simple Loop Optimizations

- Loop transformations are often used to expose other optimization opportunities:
  - Normalization
  - Loop Interchange
  - Loop Fusion
  - Loop Reversal
  - ...

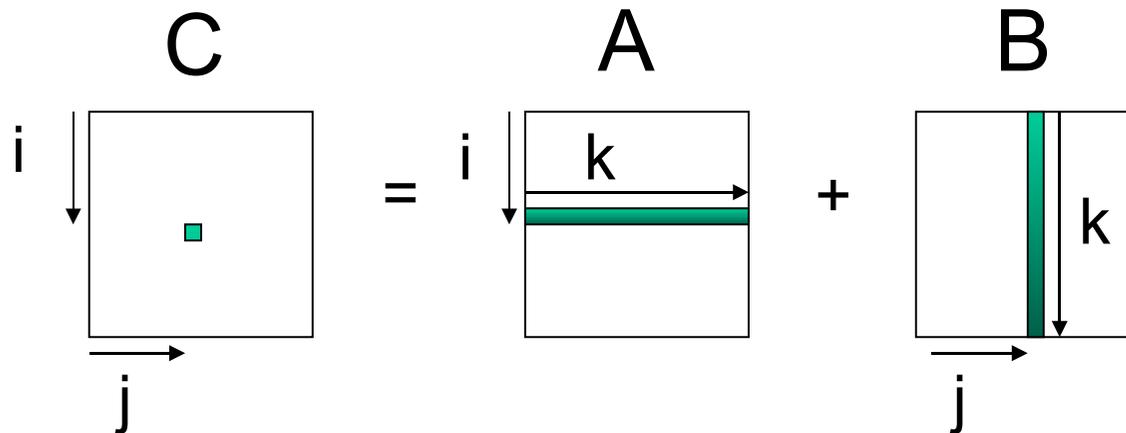

# Consider Matrix Multiplication

```
for i = 1 to n do
  for j = 1 to n do
    for k = 1 to n do
      C[i,j] = C[i,j] + A[i,k] + B[k,j]
    end
  end
end
```

# Memory Usage

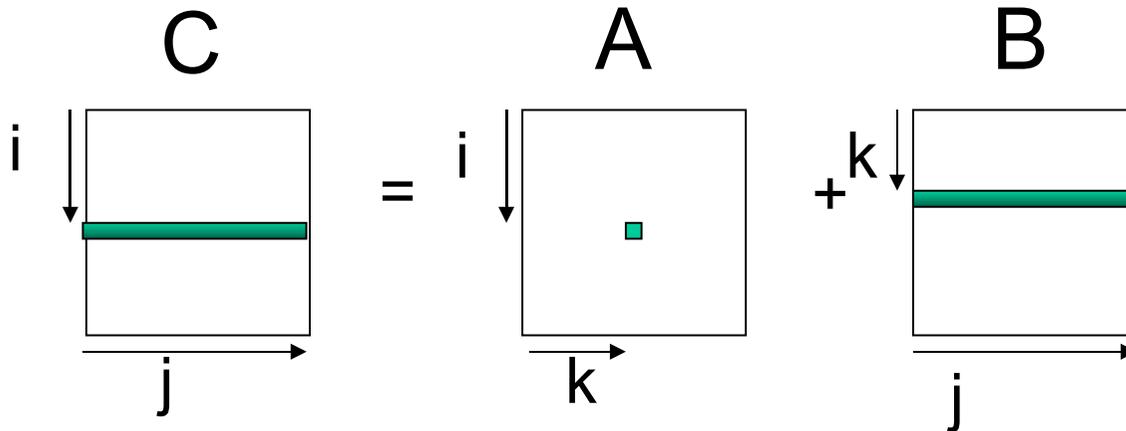

- **For A:** Elements are accessed across rows, spatial locality is exploited for cache (assuming row major storage)
- **For B:** Elements are accessed along columns, unless cache can hold all of B, cache will have problems.
- **For C:** Single element computed per loop – use register to hold

# Matrix Multiplication - Version 2

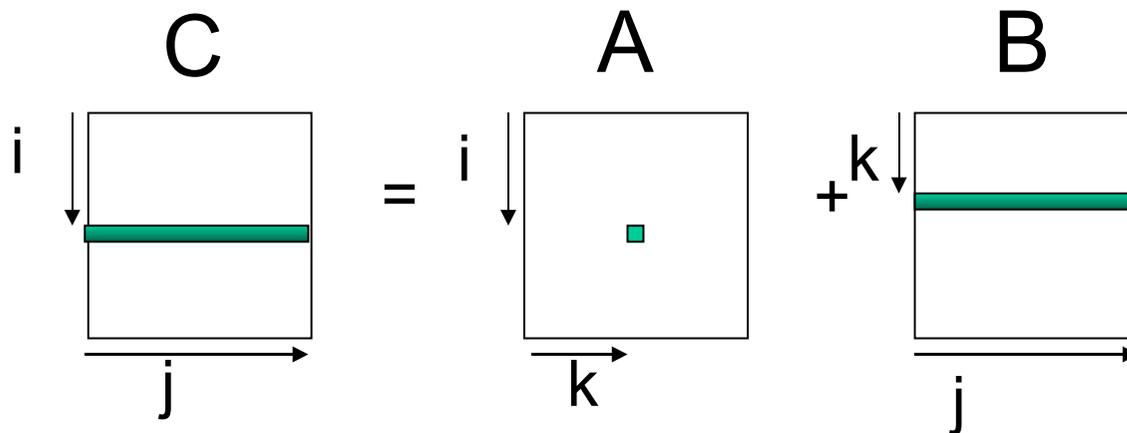

```
for i = 1 to n do
  for k = 1 to n do
    for j = 1 to n do
      C[i,j] = C[i,j] + A[i,k] + B[k,j]
    end
  end
end
end
```

loop interchange

# Memory Usage

- **For A:** Single element loaded for loop body
- **For B:** Elements are accessed along rows to exploit spatial locality.
- **For C:** Extra loading/storing, but across rows

# Simple Loop Optimizations

- How to determine safety?
  - Does the new multiply give the same answer?
  - Can be reversed?
  - **for (I=1 to N) a[I] = a[I+1]**
    - can this loop be safely reversed?

# Data Dependencies

- Flow Dependencies - write/read

`x := 4;`

`y := x + 1`

- Output Dependencies - write/write

`x := 4;`

`x := y + 1;`

- Antidependencies - read/write

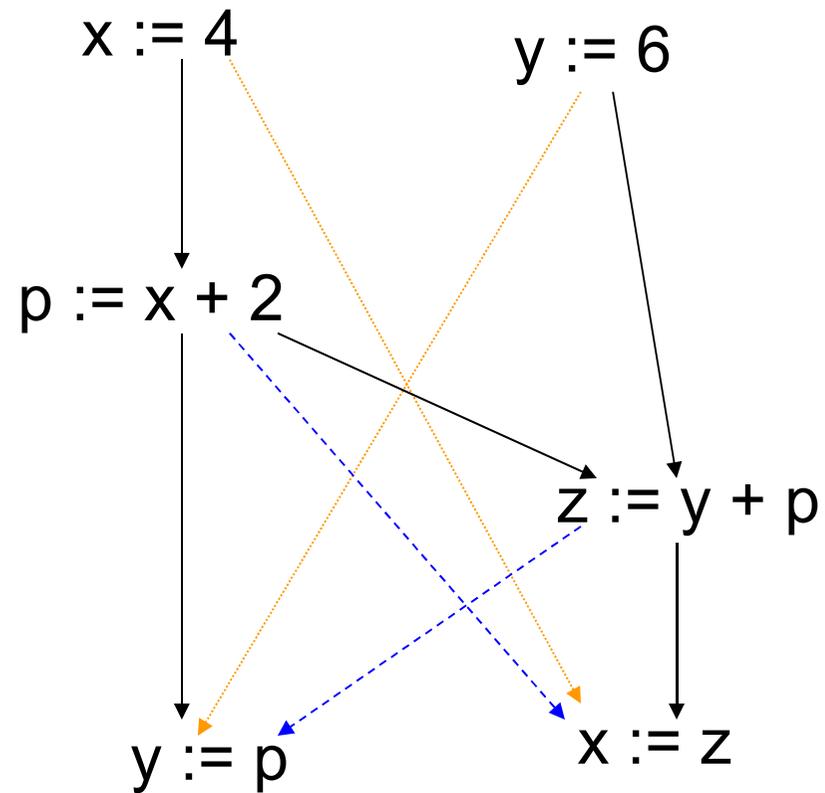

`y := x + 1;`

`x := 4;`

# Data Dependencies - Example

```
x := 4  
y := 6  
p := x + 2  
z := y + p  
x := z  
y := p
```

→ Flow  
→ Output  
→ Anti

# Global Data Flow Analysis

Collecting information about the way data is used in a program.

- Takes control flow into account
- HL control constructs
  - Simpler – syntax driven
  - Useful for data flow analysis of source code
- General control constructs – arbitrary branching
- Information needed for optimizations such as: constant propagation, common sub-expressions, partial redundancy elimination ...

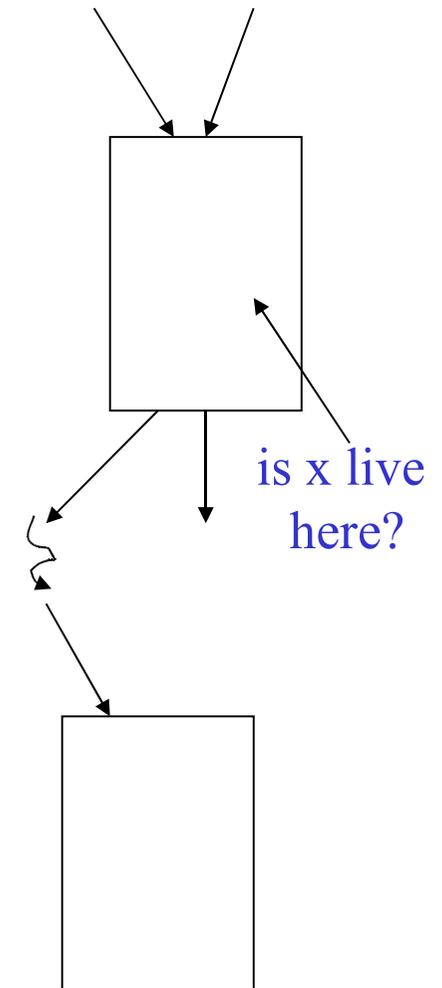

# Dataflow Analysis: Iterative Techniques

- First, compute local (block level) information
- Iterate until no changes

```
while change do
    change = false
    for each basic block
        apply equations updating IN and OUT
        if either IN or OUT changes, set change to true
    end
end
```

# Live Variable Analysis

- A variable  $x$  is *live* at a point  $p$  if there is some path from  $p$  where  $x$  is used before it is defined.
- Want to determine for some variable  $x$  and point  $p$  whether the value of  $x$  *could* be used along some path starting at  $p$ .
- Information flows backwards
- May – ‘along some path starting at  $p$ ’

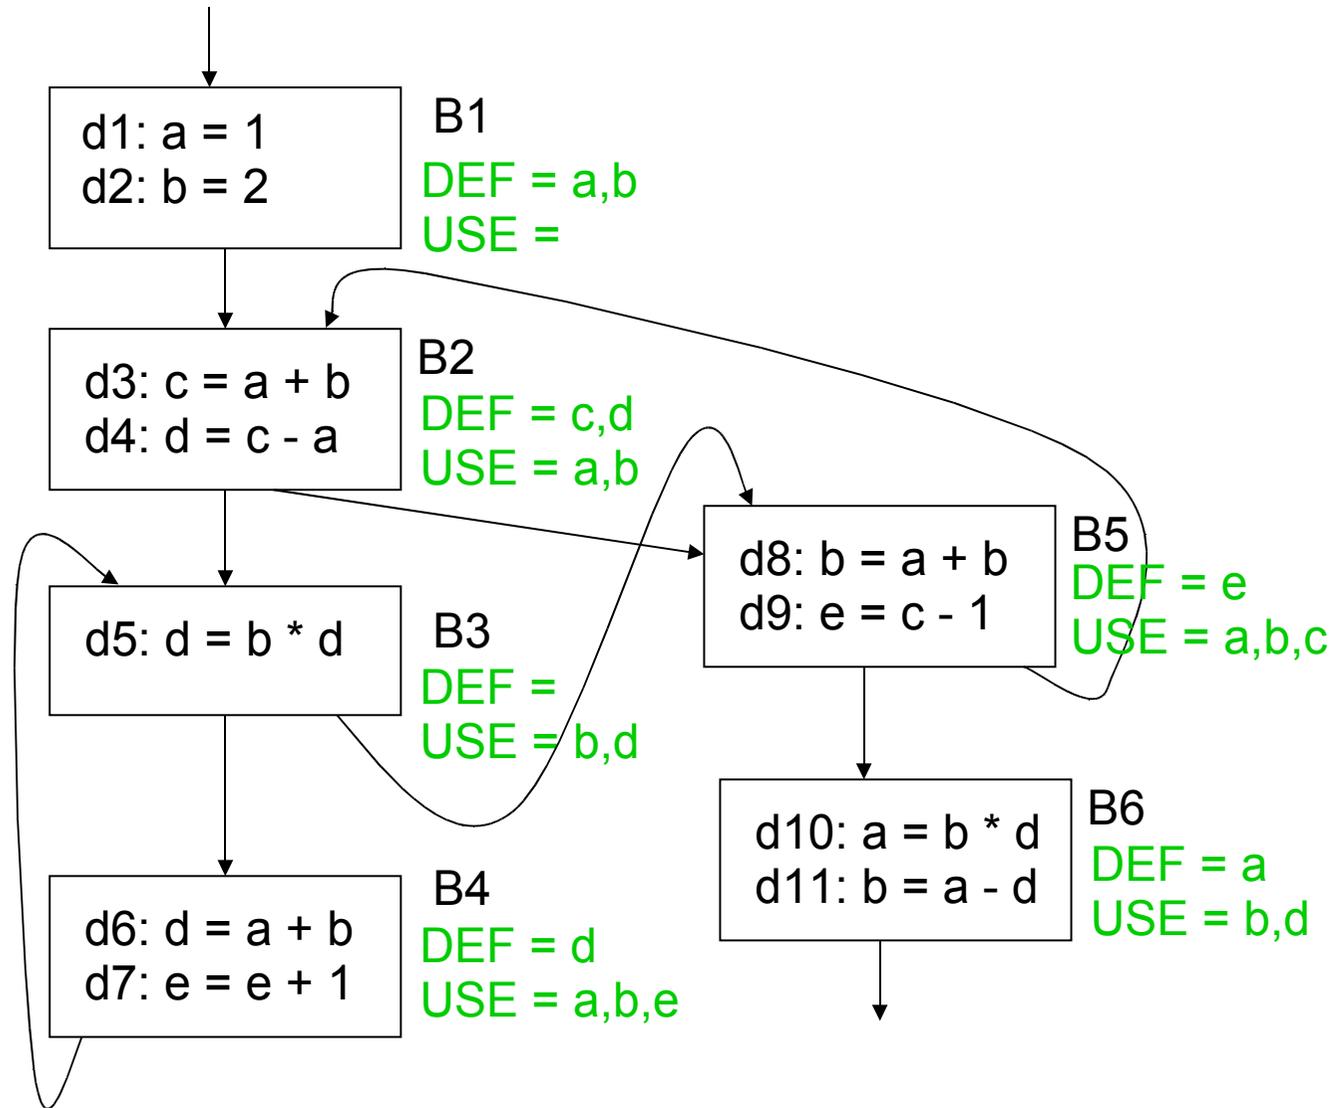

# Global Live Variable Analysis

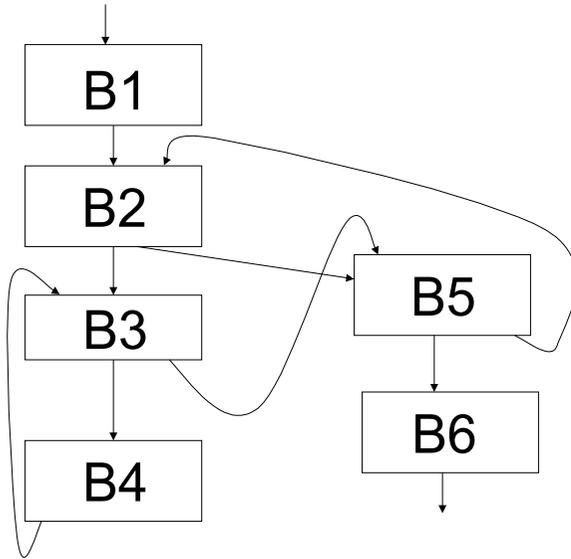

- Want to determine for some variable  $x$  and point  $p$  whether the value of  $x$  could be used along some path starting at  $p$ .
- $DEF[B]$  - set of variables assigned values in  $B$  prior to any use of that variable
- $USE[B]$  - set of variables used in  $B$  prior to any definition of that variable
- $OUT[B]$  - variables live immediately after the block  $OUT[B]$ :  
 $\cup IN[S]$  for all  $S$  in  $\text{succ}(B)$
- $IN[B]$  - variables live immediately before the block

$$IN[B] = USE[B] + (OUT[B] - DEF[B])$$

# DEF[B] and USE[B]

# Example

Block	DEF	USE
B1	{a,b}	{ }
B2	{c,d}	{a,b}
B3	{ }	{b,d}
B4	{d}	{a,b,e}
B5	{e}	{a,b,c}
B6	{a}	{b,d}

$$\text{OUT}[B] = \cup \text{IN}[S] \text{ for all } S \text{ in succ}(B)$$

$$\text{IN}[B] = \text{USE}[B] + (\text{OUT}[B] - \text{DEF}[B])$$

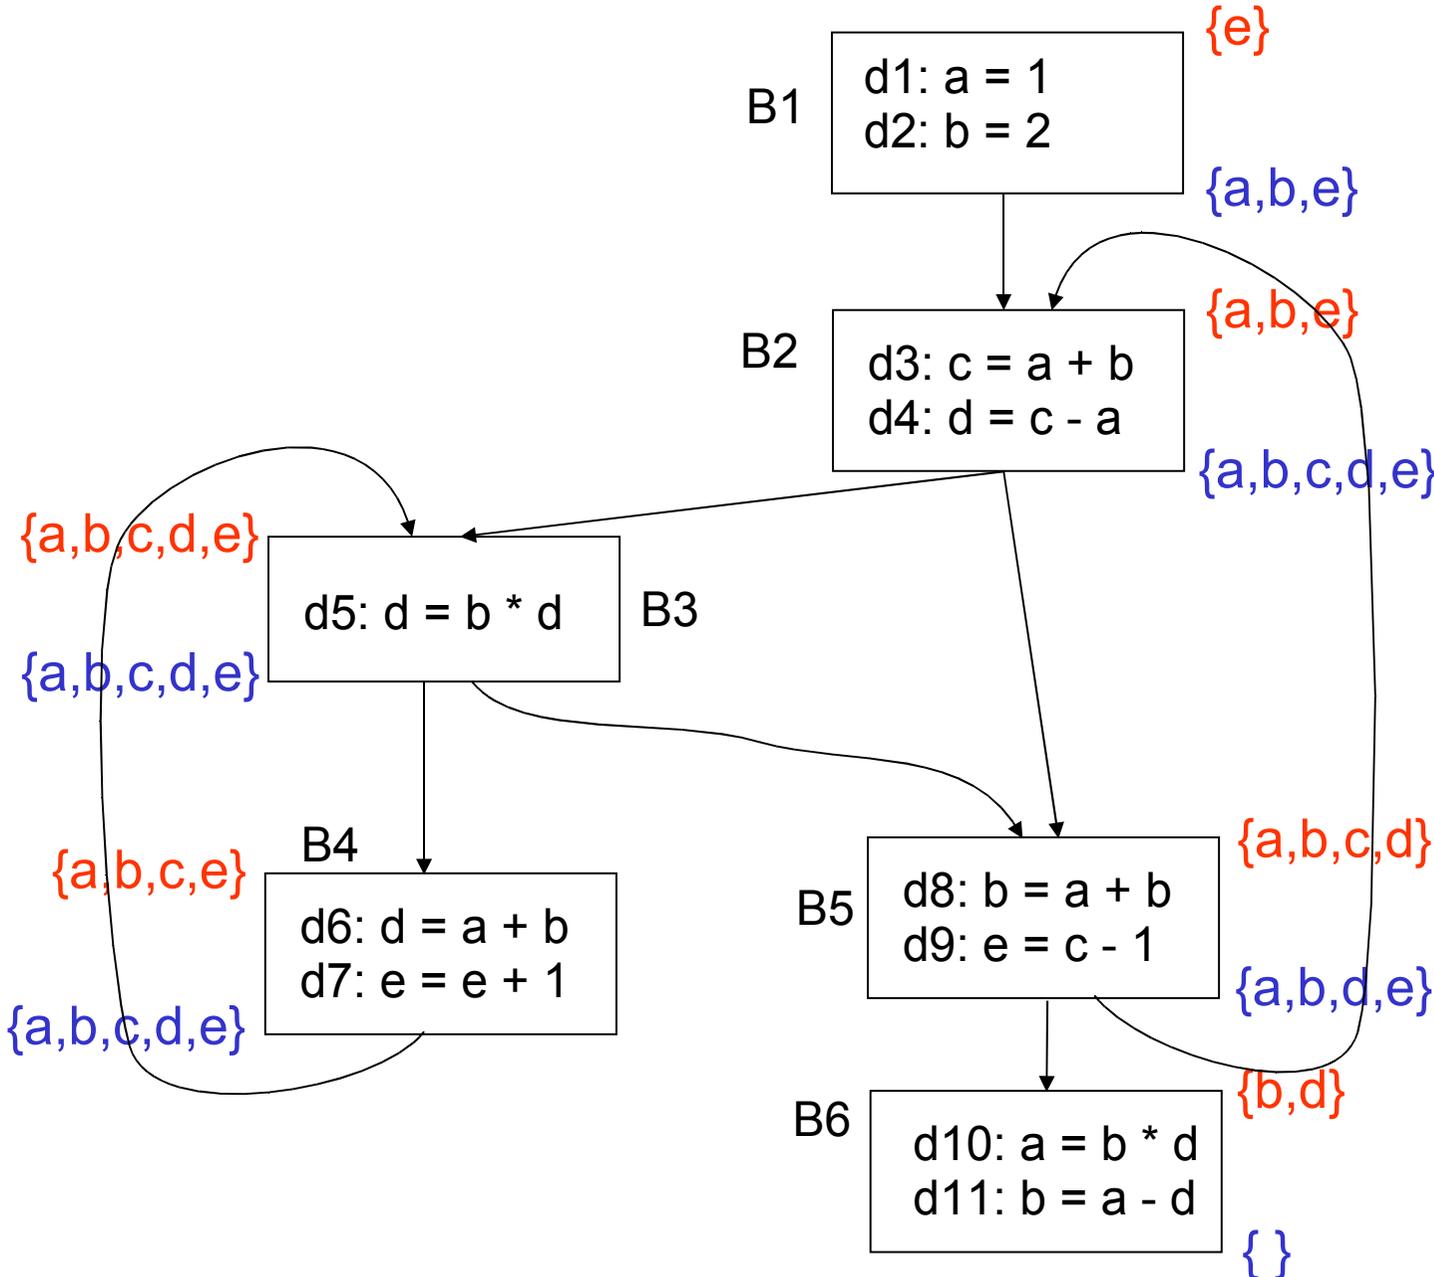

$$\begin{aligned} \text{OUT}[B1] &= \text{IN}[B2] \\ \text{IN}[B1] &= \text{OUT}[B1] - \{a,b\} \\ \text{OUT}[B2] &= \text{IN}[B3] + \text{IN}[B5] \\ \text{IN}[B2] &= \{a,b\} + (\text{OUT}[B2] - \{c,d\}) \\ \text{OUT}[B3] &= \text{IN}[B4] + \text{IN}[B5] \\ \text{IN}[B3] &= \{b,d\} + \text{OUT}[B3] \\ \text{OUT}[B4] &= \text{IN}[B3] \\ \text{IN}[B4] &= \{a,b,e\} + (\text{OUT}[B4] - \{d\}) \\ \text{OUT}[B5] &= \text{IN}[B6] + \text{IN}[B2] \\ \text{IN}[B5] &= \{a,b,c\} + (\text{OUT}[B5] - \{e\}) \\ \text{OUT}[B6] &= \emptyset \\ \text{IN}[B6] &= \{b,d\} + (\text{OUT}[B6] - \{a\}) \end{aligned}$$

	IN	OUT
B1	$\emptyset$	
B2	$\emptyset$	
B3	$\emptyset$	
B4	$\emptyset$	
B5	$\emptyset$	
B6	$\emptyset$	

# Solution

	IN	OUT	IN	OUT	IN	OUT	IN	OUT	IN
B1	∅	∅	∅	a,b	∅	a,b	∅	a,b,e	e

# CFG after Live Variable Analysis

# Dataflow Analysis Problem #2: Reachability

- A definition of a variable  $x$  is a statement that may assign a value to  $x$
- A definition may reach a program point  $p$  if there exists some path from the point immediately following the definition to  $p$  such that the assignment is not killed along that path
- Concept: relationship between definitions and uses

# What Blocks Do Definitions d2 and d4 Reach?

# Reachability Analysis: Unstructured Input

1. Compute GEN and KILL at block-level
2. Compute IN[B] and OUT[B] for B
$$\text{IN}[B] = \bigcup \text{OUT}[P] \quad \text{where } P \text{ is a predecessor of } B$$
$$\text{OUT}[B] = \text{GEN}[B] \cup (\text{IN}[B] - \text{KILL}[B])$$
3. Repeat step 2 until there are no changes to OUT sets

# Reachability Analysis: Step 1

- For each block, compute local (block level) information = GEN/KILL sets
  - $GEN[B]$  = set of definitions generated by B
  - $KILL[B]$  = set of definitions that can not reach the end of B
- This information does not take control flow between blocks into account

# Reasoning about Basic Blocks

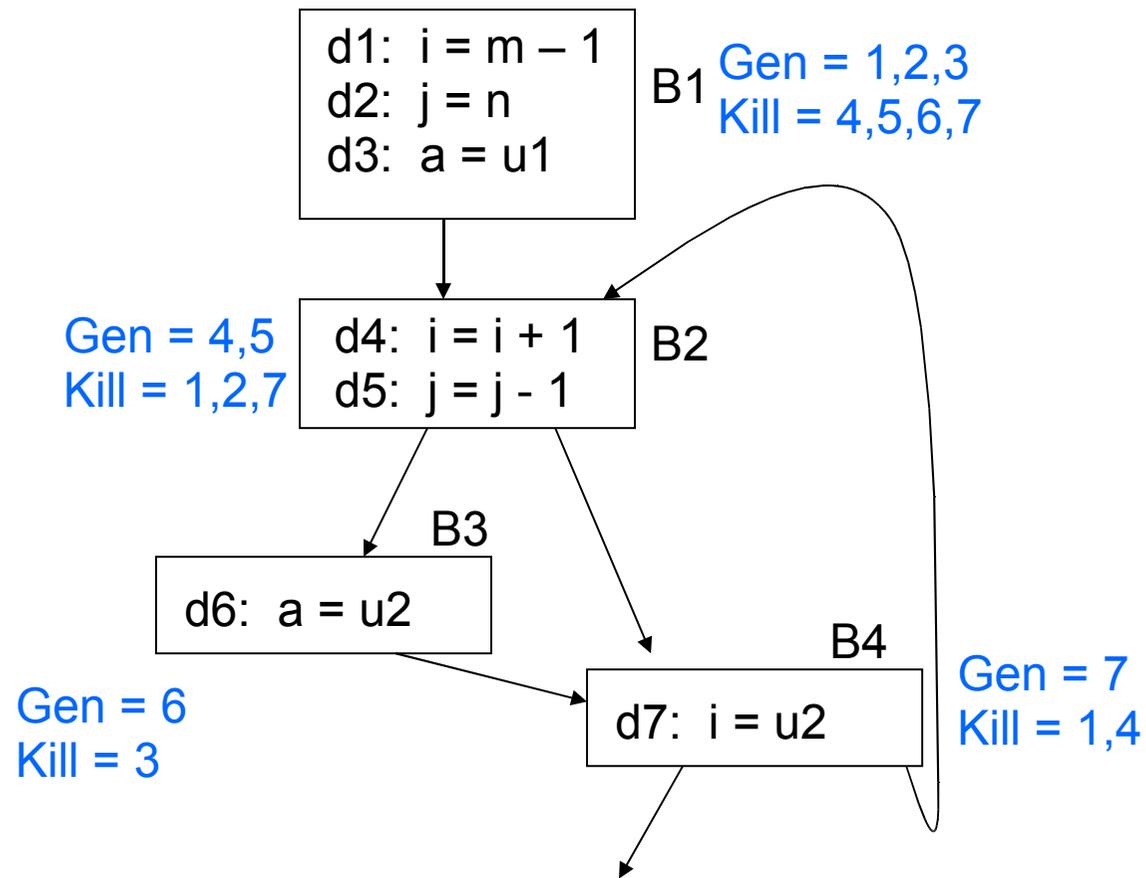

Effect of single statement:  $a = b + c$

- Uses variables  $\{b,c\}$
- **Kills all definitions of  $\{a\}$**
- **Generates new definition (i.e. assigns a value) of  $\{a\}$**

Local Analysis:

- Analyze the effect of each instruction
- Compose these effects to derive information about the entire block

# Example

# Reachability Analysis: Step 2

- Compute IN/OUT for each block in a forward direction.  
Start with  $IN[B] = \emptyset$ 
  - $IN[B] = \text{set of defns reaching the start of } B$   
 $= \cup (\text{out}[P])$  for all predecessor blocks in the CFG
  - $OUT[B] = \text{set of defns reaching the end of } B$   
 $= GEN[B] \cup (IN[B] - KILL[B])$
- Keep computing IN/OUT sets until a fixed point is reached

# Reaching Definitions Algorithm

- Input: Flow graph with GEN and KILL for each block
- Output:  $in[B]$  and  $out[B]$  for each block.

For each block B do  $out[B] = gen[B]$ , (true if  $in[B] = \text{emptyset}$ )

change := true;

while change do begin

    change := false;

    for each block B do begin

$in[B] := \bigcup out[P]$ , where P is a predecessor of B;

        oldout = out[B];

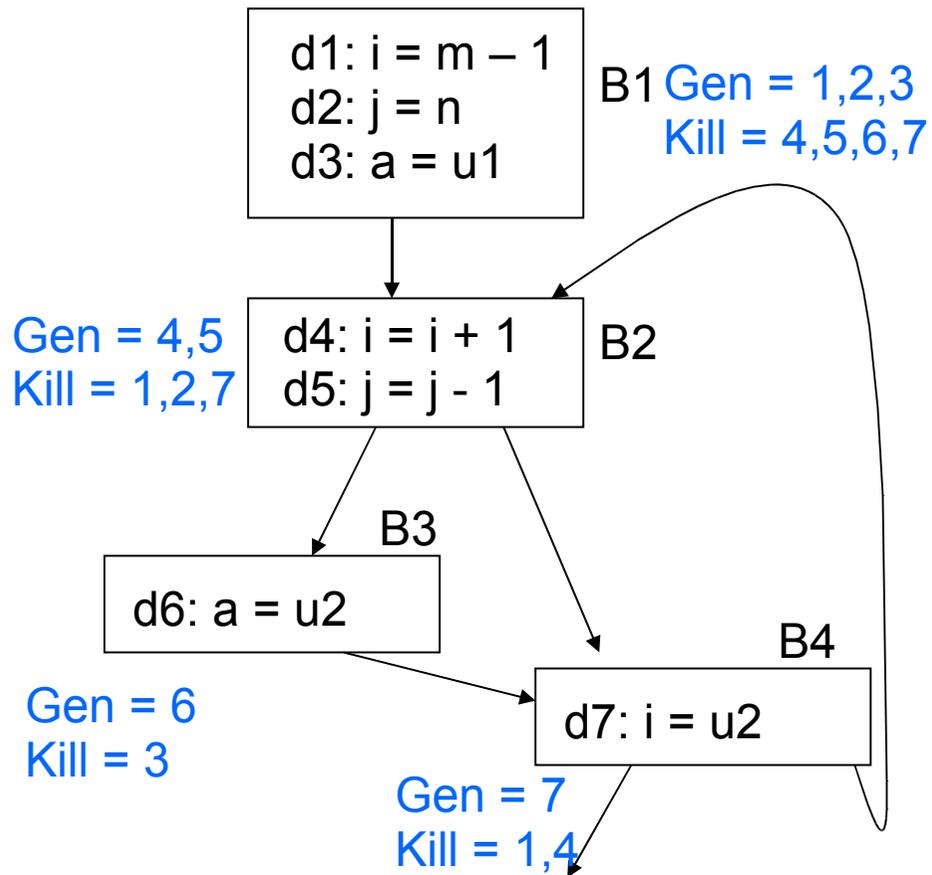

$out[B] := gen[B] \cup (in[B] - kill [B])$

        if  $out[B] \neq oldout$  then change := true;

    end

end

# Reaching Definitions Example

	IN	OUT		
B1	$\emptyset$	1,2,3		
B2	$\emptyset$	4,5		
B3	$\emptyset$	6		
B4	$\emptyset$	7		

$IN[B] = \cup(out[P])$  for all predecessor blocks in the CFG

$OUT[B] = GEN[B] \cup (IN[B] - KILL[B])$

# Reaching Definitions Example

$IN[B] = \cup(out[P])$  for all predecessor blocks in the CFG

$OUT[B] = GEN[B] + (IN[B] - KILL[B])$

	IN	OUT	IN	OUT
B1	$\emptyset$	1,2,3	$\emptyset$	1,2,3
B2	$\emptyset$	4,5	$OUT[1]+OUT[4]$ $= 1,2,3,7$	$4,5 + (1,2,3,7 - 1,2,7)$ $= 3,4,5$
B3	$\emptyset$	6	$OUT[2] = 3,4,5$	$6 + (3,4,5 - 3)$ $= 4,5,6$
B4	$\emptyset$	7	$OUT[2]+OUT[3]$ $= 3,4,5,6$	$7 + (3,4,5,6 - 1,4)$ $= 3,5,6,7$

# Reaching Definitions Example

$IN[B] = \cup(out[P])$  for all predecessor blocks in the CFG

$OUT[B] = GEN[B] + (IN[B] - KILL[B])$

	IN	OUT	IN	OUT	IN	OUT
B1	$\emptyset$	1,2,3	$\emptyset$	1,2,3	$\emptyset$	1,2,3
B2	$\emptyset$	4,5	1,2,3,7	3,4,5	$OUT[1] + OUT[4]$ $= 1,2,3,5,6,7$	$4,5 +$ $(1,2,3,5,6,7 - 1,2,7)$ $= 3,4,5,6$
B3	$\emptyset$	6	3,4,5	4,5,6	$OUT[2] = 3,4,5,6$	$6 + (3,4,5,6 - 3)$ $= 4,5,6$
B4	$\emptyset$	7	3,4,5,6	3,5,6,7	$OUT[2] + OUT[3]$ $= 3,4,5,6$	$7 + (3,4,5,6 - 1,4)$ $= 3,5,6,7$

# Forward vs. Backward

- Forward flow vs. Backward flow
  - Forward: Compute OUT for given IN, GEN, KILL
    - Information propagates from the predecessors of a vertex
    - Examples: **Reachability**, available expressions, constant propagation
  - Backward: Compute IN for given OUT, GEN, KILL
    - Information propagates from the successors of a vertex
    - Example: **Live variable analysis**

# Forward vs. Backward Equations

- Forward vs. backward
  - Forward:
    - $IN[B]$  - process  $OUT[P]$  for all  $P$  in predecessors( $B$ )
    - $OUT[B] = local \cup (IN[B] - local)$
  - Backward:
    - $OUT[B]$  - process  $IN[S]$  for all  $S$  in successor( $B$ )
    - $IN[B] = local \cup (OUT[B] - local)$

# May vs. Must

## May vs. Must

Must – true on **all paths**

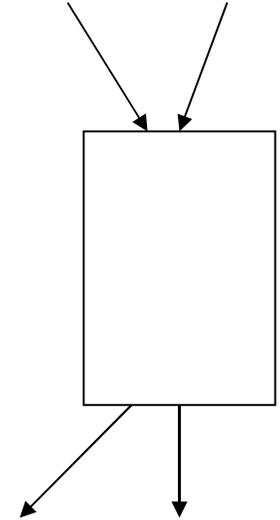

Ex: constant propagation – variable must provably hold appropriate constant on all paths in order to do a substitution

May – true on **some path**

Ex: **Live variable analysis** – a variable is live if it could be used on some path; **reachability** – a definition reaches a point if it can reach it on some path

# May vs. Must Equations

- May vs. Must
  - May –  $IN[B] = \cup(out[P])$  for all  $P$  in  $pred(B)$
  - Must –  $IN[B] = \cap(out[P])$  for all  $P$  in  $pred(B)$

# Example Equations

- **Reachability**

- $IN[B] = \cup(\text{out}[P])$  for all  $P$  in  $\text{pred}(B)$
- $OUT[B] = \text{GEN}[B] + (IN[B] - \text{KILL}[B])$

- **Live Variable Analysis**

- $OUT[B] = \cup(IN[S])$  for all  $S$  in  $\text{succ}(B)$
- $IN[B] = \text{USE}[B] \cup (OUT[B] - \text{DEF}[B])$

- **Constant Propagation**

- $IN[B] = \cap(\text{out}[P])$  for all  $P$  in  $\text{pred}(B)$
- $OUT[B] = \text{DEF\_CONST}[B] \cup (IN[B] - \text{KILL\_CONST}[B])$

# Discussion

- Why does this work?
  - Finite set – can be represented as bit vectors
  - Theory of lattices
- Is this guaranteed to terminate?
  - Sets only grow and since finite in size ...
- Can we find ways to reduce the number of iterations?

# Choosing Visit Order for Dataflow Analysis

- In forward flow analysis situations, if we visit the blocks in depth first order, we can reduce the number of iterations
- Suppose definition  $d$  follows block path  $3 \rightarrow 5 \rightarrow 19 \rightarrow 35 \rightarrow 16 \rightarrow 23 \rightarrow 45 \rightarrow 4 \rightarrow 10 \rightarrow 17$  where the block numbering corresponds to the preorder depth-first numbering
- Then we can compute the reach of this definition in 3 iterations of our algorithm

$3 \rightarrow 5 \rightarrow 19 \rightarrow 35 \rightarrow 16 \rightarrow 23 \rightarrow 45 \rightarrow 4 \rightarrow 10 \rightarrow 17$
